DBMS_SEARCH

The `DBMS_SEARCH` package enables the indexing of multiple schema objects in a single index.

This Oracle Text package provides procedures and functions to create, maintain, and query a ubiquitous search index. Ubiquitous database search is a full-text and range-based search across multiple tables and views. To add data sources from different schemas to the index, the index owner must have `SELECT` and `DML` access to the sources.

A complete description of this package is available in *Oracle Text Reference*.
